EP 1 113 007 A1

Description

[0001] This invention relates to novel tetrahydroisoquinoline compounds that are useful as estrogen agonists and antagonists, and the pharmaceutical uses thereof.

5

BACKGROUND OF THE INVENTION

[0002] The value of naturally occurring estrogens and synthetic compositions demonstrating "estrogenic" activity has typically been in their medical and therapeutic uses. A traditional listing of the therapeutic applications for estrogens alone or in combination with other active agents includes, but is not limited to, oral contraception, relief for the symptoms of menopause, prevention of threatened or habitual abortion, relief of dysmenorrhea, relief of dysfunctional uterine bleeding, an aid in ovarian development, treatment of acne, diminution of excessive growth of body hair in women (hirsutism), the prevention of cardiovascular disease, treatment of osteoporosis, treatment of prostatic carcinoma, and suppression of post-partum lactation (Goodman and Gilman, *The Pharmacological Basis Of Therapeutics* (7th Ed.), Macmillan Publishing Company, 1985, pages 1421-1423). Accordingly, there has been increasing interest in finding newly synthesized compounds and new uses for previously known compounds that are demonstrably estrogenic, that is, able to mimic the action of estrogen in estrogen responsive tissue.

10

[0003] From the viewpoint of pharmacologists interested in developing new drugs useful for the treatment of human diseases and specific pathological conditions, it is desirable to procure compounds having demonstrable estrogen-like function, but which are devoid of unwanted side-effects. Exemplifying this latter view, osteoporosis, a disease in which bone becomes increasingly more fragile, is greatly ameliorated by the use of fully active estrogens. However, due to the recognized increased risk of uterine cancer in patients treated chronically with active estrogens, it is not clinically advisable to treat osteoporosis in intact women with fully active estrogens for prolonged periods.

15

[0004] Osteoporosis is a systemic skeletal disease, characterized by low bone mass and deterioration of bone tissue, with a consequent increase in bone fragility and susceptibility to fracture. In the U.S., the condition affects more than 25 million people and causes more than 1.3 million fractures each year, including 500,000 spine, 250,000 hip, and 240,000 wrist fractures annually. These injuries cost the nation over \$10 billion per year. Hip fractures are the most serious, with 5-20% of patients dying within one year, and over 50% of the survivors being incapacitated.

20

[0005] The elderly are at greatest risk of osteoporosis, and the problem is therefore predicted to increase significantly with the aging of the population. Worldwide fracture incidence is forecast to increase 3-fold over the next 60 years, and one study estimates there will be 4.5 million hip fractures worldwide in 2050.

25

[0006] Women are at greater risk of osteoporosis than men. Women experience a sharp acceleration of bone loss during the five years following menopause. Other factors that increase the risk include smoking, alcohol abuse, a sedentary lifestyle, and low calcium intake.

30

[0007] Estrogen is the agent of choice in preventing osteoporosis or post menopausal bone loss in women; it is the only treatment that unequivocally reduces fractures. However, estrogen stimulates the uterus and is associated with an increased risk of endometrial cancer. Although the risk of endometrial cancer is thought to be reduced by a concurrent use of a progestogen, there remains concern about possible increased risk of breast cancer with the use of estrogen.

35

[0008] Black et al., in EP 0605193A1, report that estrogen, particularly when taken orally, lowers plasma levels of LDL and raises plasma levels of the beneficial high density lipoproteins (HDLs). Thus, estrogen can be an effective therapy for hypercholesterolemia. However, as discussed supra, long-term estrogen therapy has been implicated in a variety of disorders, including an increase in the risk of uterine and breast cancer, causing many women to avoid this treatment. Recently suggested therapeutic regimens, that seek to lessen the cancer risk, such as administering combinations of progestogen and estrogen, cause the patient to experience unacceptable bleeding. Furthermore, combining progestogen with estrogen seems to blunt the desired serum cholesterol effects of estrogen. The significant undesirable effects associated with estrogen therapy support the need to develop alternative therapies for hypercholesterolemia that have the desirable effect on serum LDL but do not cause undesirable effects.

40

[0009] There is a need for improved estrogen agonists that exert selective effects on different tissues in the body. Tamoxifen, or 1-(4- β -dimethylaminoethoxyphenyl)-1,2-diphenyl-but-1-ene, is an antiestrogen that has a palliative effect on breast cancer, but is reported to have estrogenic activity in the uterus. Gill-Sharma et al., *J. Repr. Fert.*, 99:395 (1993), discloses that tamoxifen at 200 and 400 mg/kg/day reduces the weights of the testes and secondary sex organs in male rats.

45

[0010] Recently it has been reported (Osteoporosis Conf. Scrip No. 1812/13, p. 29 (April 16-20, 1993)) that raloxifene, or 6-hydroxy-2-(4-hydroxyphenyl)-3-[4-(2-piperidinoethoxy) benzoyl] benzo[b] thiophene, mimics the favorable action of estrogen on bone and lipids but, unlike estrogen, has minimal uterine stimulatory effect. (Jordan et al., *Breast Cancer Res. Treat.*, 10(1):31-36 (1987)).

50

[0011] Neubauer et al., *The Prostate*, 23:245 (1993), teaches that raloxifene treatment of male rats produced regression of the ventral prostate.

[0012] Raloxifene and related compounds are described as antiestrogenic and antiandrogenic materials that are effective in the treatment of certain mammary and prostate cancers. See U.S. Patent 4,418,068 and Jones et al., *J. Med. Chem.*, 27:1057-66 (1984).

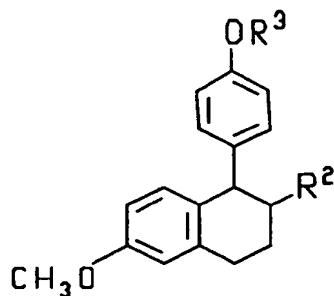

5 [0013] Jones et al. in U.S. Patent 4,133,814 describe derivatives of 2-phenyl-3-aryl-benzothiophene and 2-phenyl-3-arylbenzothiophene-1-oxides that are useful as antifertility agents, and also suppress the growth of mammary tumors.

[0014] Lednicer et al., *J. Med. Chem.*, 12:881 (1969), describes estrogen antagonists of the structure

Scheme A

- [0083] As illustrated in Scheme A, a phenethyl amine of formula (II) is coupled with a carboxylic acid of formula (III) to give the benzamide of formula (V). Compound (V) is subjected to cyclodehydration to give the dihydroisoquinoline of formula (VI). Dihydroisoquinoline (VI) is reduced to the tetrahydroisoquinoline of formula (VII). Then, compound (VII) may be reacted with a desired acid anhydride, acid chloride, or other coupling agent to give compound (Ia). Alternatively, compound (VII) may be reacted with a desired acid in the presence of 1-propanephosphonic acid cyclic anhydride, Et_3N , and DMAP in dichloromethane (CH_2Cl_2) to yield compound (Ia).
- [0084] The coupling of compounds (II) and (III) is carried out in the presence of a coupling agent for peptide synthesis, preferably with an additive. Suitable coupling agents include water-soluble diimides such as N-cyclohexyl-N'-(4-diethylaminocyclohexyl)-carbodiimide and 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide (EDC), and suitable additives include 1-hydroxybenzotriazole (HOBT) and 3-hydroxy-4-oxo-3,4-dihydro-1,2,3-benzotriazine. This reaction mixture is preferably stirred at a temperature between about 0°C to room temperature (i.e., about 25°C), for about 12 to 60 hours in a reaction inert solvent such as CH_2Cl_2 , preferably under nitrogen.
- [0085] Cyclodehydration of the intermediate compound (V) is carried out in a reaction inert solvent such as 1,2-dichloroethane in the presence of phosphorus pentachloride under nitrogen, or neat using phosphorus oxychloride under nitrogen. Phosphorus pentachloride is added to the solution of compound (V) at about 0°C, then the reaction mixture is refluxed for about 1 to 24 hours. The reaction of compound (V) and phosphorus oxychloride is carried out at about the reflux temperature of the reaction mixture for about 1 to 48 hours.
- [0086] The reduction of compound (VI) to compound (VII) is typically carried out in the presence of sodium borohydride in a reaction inert solvent such as methanol or tetrahydrofuran, at from about 0°C to about room temperature,

for about 1 to 12 hours, preferably under nitrogen. The reaction is quenched with water.

[0087] The intermediate compound (VII) thus obtained is reacted with a desired acid anhydride or acid chloride to yield compound (Ia) according to amide formation procedures known to those skilled in the art. This reaction is performed in the presence of a base such as triethylamine (Et_3N), in a reaction inert solvent such as CH_2Cl_2 , for about 1 to 72 hours, at about 0°C to about room temperature. This reaction is preferably performed under nitrogen.

[0088] Alternatively, compound (V) may be prepared by reacting compound (II) with an acyl chloride of formula (IV) in the presence of a base such as triethylamine in a reaction inert solvent. Suitable solvents include dichloromethane, tetrahydrofuran (THF), CHCl_3 , 1,2-dichloroethane, dioxane, toluene, benzene, and the like, with THF being the most preferred. This reaction is preferably carried out at a temperature of about 0°C to 30°C, most preferably about 25°C, under nitrogen, for about 1 to 24 hours, preferably about 12 hours. If required, a catalyst such as 4-(dimethylamino)pyridine, scandium triflate, tributyl phosphine, or the like may be added to the reaction mixture.

[0089] Intermediate compound (VI) may be substituted with a desired substituent on R^1 and subsequently subjected to the remaining processes illustrated in Scheme A. This substitution reaction is performed according to procedures known to those skilled in the art. For example, compound (VI) wherein R^1 is piperidin-4-yl may be reacted with a heteroaryl sulfonyl chloride in the presence of a base such as triethylamine in a reaction inert solvent such as dichloroethane to yield a sulfonamide. This reaction is preferably carried out at about room temperature, under nitrogen, for about 1 to 24 hours, preferably about 2 to 20 hours.

[0090] A compound of formula (I) of this invention wherein X is $-(\text{CH}_2)_z-\text{SO}_2-$ may be prepared by reacting compound (VII) with a sulfonyl chloride of formula $\text{R}^2-(\text{CH}_2)_z-\text{SO}_2-\text{Cl}$ according to known procedures. For example, this reaction may be carried out in the presence of triethylamine in a reaction inert solvent such as tetrahydrofuran (THF) at about room temperature for about 1 to 24 hours under nitrogen.

[0091] A compound of formula (I) of this invention wherein X is a covalent bond, $(\text{CH}_2)_n$, or $(\text{CH}_2)_x\text{-phenyl}$ (wherein x is 0 or 1), may also be prepared by reacting compound (VII) with an aldehyde of formula $\text{R}^2\text{-X-CHO}$ according to known procedures. This reaction is typically performed in the presence of a reducing agent such as sodium cyanoborohydride in a suitable solvent such as methanol.

[0092] A compound of formula (I) of this invention wherein X is CO_2 may be prepared by reacting compound (VII) with either a dicarbonate of formula $(\text{R}^2\text{OCO})_2\text{O}$ or a chloroformate of formula R^2OCOCl in the presence of a base such as triethylamine in a suitable solvent such as THF at about room temperature for about 1 to 24 hours, preferably under nitrogen.

55

Scheme B

[0094] A benzyl acid of formula (VIII) is reacted with an amine of formula (IX) to give an amide, which is then reduced (this step not shown) to give thephenethyl amine of formula (X) according to known procedures (see, for example, Nagarajan et al., *Ind. J. Chem.*, 24B:83-97 (1985)). Compound (X) thus obtained is reacted with a carboxylic acid of formula (XI) to give the benzamide of formula (XII). The compound of formula (XII) is subjected to cyclodehydration followed by reduction, preferably with NaBH_4 in methanol, to give the tetrahydroisoquinoline (Ib).

[0095] The reaction of compound (X) with compound (XI) is carried out in the presence a base such as triethylamine, in a reaction inert solvent such as dichloromethane, THF, CHCl₃, or dioxane, preferably in the presence of a coupling agent such as 1-propanephosphonic acid cyclic anhydride (PPAA), EDC, or a mixture thereof, and a catalytic amount of an additive such as HOBt or 4-dimethylaminopyridine (DMAP), at about 0°C to room temperature for about 1 to 36 hours.

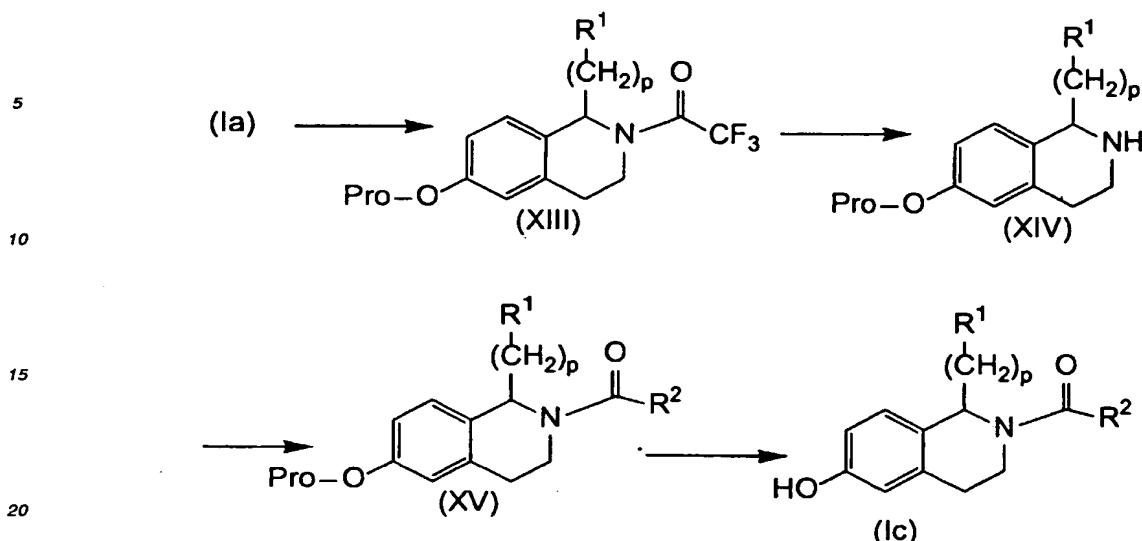

[0096] The cyclodehydration of compound (XII) may be carried out according to procedures analogous to those described for in Scheme A.

[0097] Alternatively, compound (X) may be reacted with an acyl chloride of formula (IV) to give an amide (XII). This reaction may be performed according to procedures analogous to those described in Scheme A.

[0098] Compound (XI) may be substituted at its R¹ moiety with a desired substituent. For example, when R¹ is aryl aldehyde, compound (XI) is coupled with a carboalkoxytriphenylphosphorane in the presence of a base such as sodium hydroxide in a reaction inert solvent such as tetrahydrofuran (THF). This reaction is performed at about room temperature for about 1 to 12 hours.

45 General Reaction Scheme C

[0099] Scheme C illustrates methods to produce a compound of formula (Ic), namely a compound of formula (I) wherein A₁ is hydroxy and X is a covalent bond, (CH₂)_n, or (CH₂)_x-phenyl (wherein x is 0 or 1), starting from a compound of formula (Ia). In this scheme, "Pro" is a hydroxy protecting group.

Scheme C

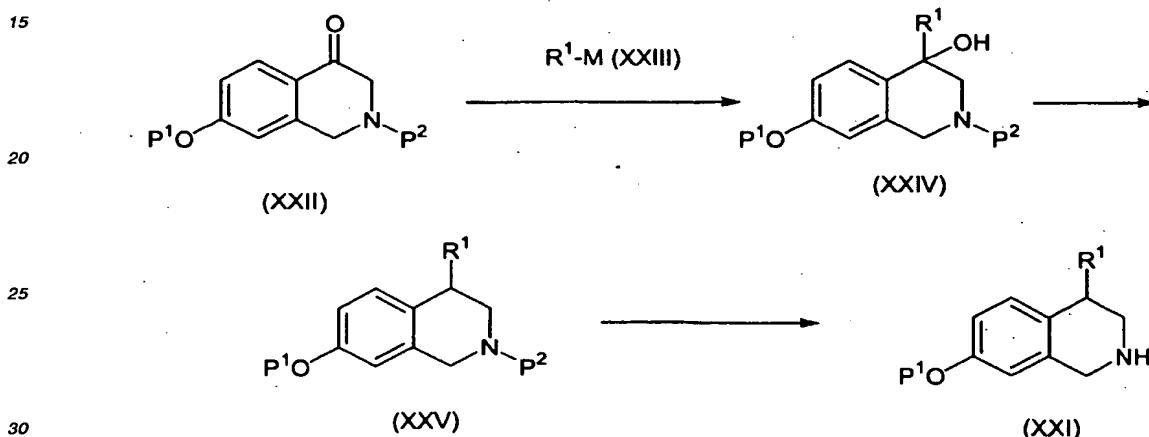

- [0100] For example, compound (Ia) wherein A₁ is hydroxy, X is CO, and R² is CF₃ is first protected with a suitable hydroxy protecting group to obtain the compound of formula (XIII), which is converted to the compound of formula (XIV), which is coupled with a suitable acyl chloride of formula R²COCl to obtain the compound of formula (XV), which is finally deprotected to yield the desired compound (Ic).
- [0101] While any hydroxy protecting groups known to those skilled in the art may be used to protect compound (Ia), a benzyl or methyl group is preferably used. The protection is typically carried out by reacting compound (Ia) wherein A₁ is hydroxy with benzyl bromide in the presence of sodium hydride in a reaction inert solvent such as DMF at about 0°C to 100°C under nitrogen for about 1 to 12 hours, preferably about 4 hours.
- [0102] Conversion of compound (XIII) is performed according to known procedures. This conversion is conveniently carried out in the presence of an inorganic base such as K₂CO₃, in a reaction inert solvent such as methanol or ethanol under N₂ for about 1 to 24 hours, preferably about 12 to 24 hours.
- [0103] The coupling reaction of compound (XIV) with a desired acyl chloride of formula R²COCl is preferably performed in the presence of triethylamine in THF at about room temperature under nitrogen for about 1 to 24 hours.
- [0104] The hydroxy protecting group of compound (XV) may be removed by known procedures. For example, this reaction may be performed in the presence of a source of H₂ and a catalyst such as 20% Pd(OH)₂/C, in a reaction inert solvent such as methanol, under nitrogen, at about the reflux temperature of the reaction mixture for about 1 to 4 hours.
- [0105] Compound (I) wherein R¹ is aryl substituted by an alkenylamide group may be obtained by reacting compound (I) wherein R¹ is iodophenyl with a suitable alkenylamide. This reaction may be performed in the presence of a catalyst such as Pd(PPh₃)₄ and a base such as triethylamine in a reaction inert solvent such as N,N-dimethylformamide (DMF) at about 60°C to 100°C for about 1 to 12 hours. The alkenylamide may be prepared by known methods, for example, by reacting a secondary amine with an acyl halide such as acryloyl chloride. This reaction is performed in the presence of a base such as triethylamine in a reaction inert solvent such as dichloroethane at about room temperature for about 1 to 12 hours.
- [0106] Compound (I) wherein A₁ is hydroxy may be obtained by converting compound (Ia) wherein A₁ is methoxy. This conversion is performed in the presence of boron tribromide in a suitable solvent such as dichloromethane at about -78°C to room temperature under nitrogen for about 1 to 12 hours. If required, this conversion may be quenched by adding a suitable solvent such as methanol.
- [0107] The hydroxy group at the 6-position of the tetrahydroisoquinoline ring of compound (I) may be converted into an optionally substituted (C₁-C₄ alkyl)-CO. For example, the hydroxy may be coupled with 1-(2-chloroethyl)pyrrolidine hydrochloride in the presence of a condensing agent such as sodium hydride in a reaction inert solvent such as DMF. This reaction is preferably performed at about room temperature to the reflux temperature of the reaction mixture, more preferably at about 100°C, under nitrogen, for about 1 to 8 hours, preferably about 4 to 5 hours.

[0108] A substituent attached to a ring moiety of R¹ of compound (I) may be converted to another substituent. For example, the hydroxy substituent on the R¹ ring moiety may be converted to 2-pyrrolidin-1-yl-ethoxy according to procedures analogous to those for the coupling reaction of hydroxy at the 6-position of the tetrahydroisoquinoline ring of compound (I) with 1-(2-chloroethyl)pyrrolidine hydrochloride.

5 [0109] Compounds (II), (III), (IV), (VIII), (IX) and (XI) are known compounds and are readily prepared according to procedures well known to those skilled in the art.

General Reaction Scheme D

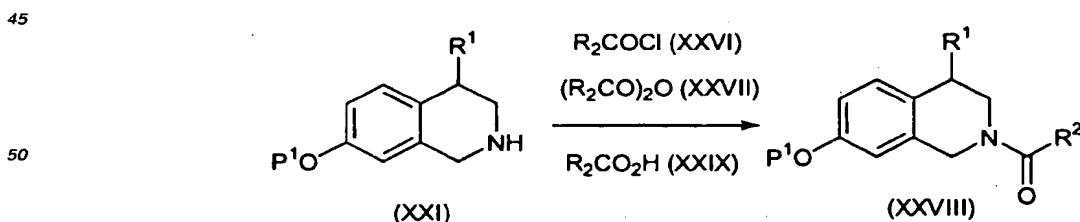

10 [0110] A compound of formula (XXI) (i.e., a compound of formula (II) lacking the R² group) may be prepared according to the procedures illustrated in Scheme D.

Scheme D

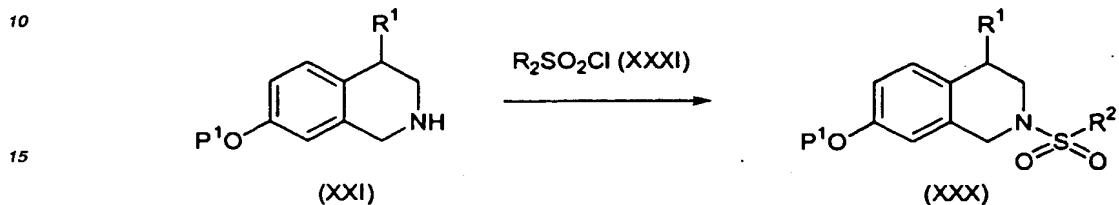

35 [0111] Compounds of formula (XXI) can be prepared under standard reaction conditions analogous to those well known in the art (e.g., Grethe et al., *J. Org. Chem.*, 33(2):491 (1968)). For example a suitably protected dihydro-1H-isoquinolin-4-one of formula (XXII) can be treated with a nucleophile of formula (XXIII) such as substituted phenyl lithium to give the alcohol of formula (XXIV). The reaction is typically run in an inert solvent such as THF, 1,2 dimethoxyethane, or diethyl ether, and a temperature range of -78°C to room temperature is preferred.

40 [0112] The alcohol (XXIV) can be reduced to the tetrahydroisoquinoline of formula (XXV) under suitable conditions (e.g., hydrogenation over a metal catalyst such as palladium). Another option for the reaction is to perform the reduction with a trialkylsilane in the presence of a strong acid such as trifluoroacetic acid. The reaction is typically run in an inert solvent at a temperature range of 0°C to 60°C.

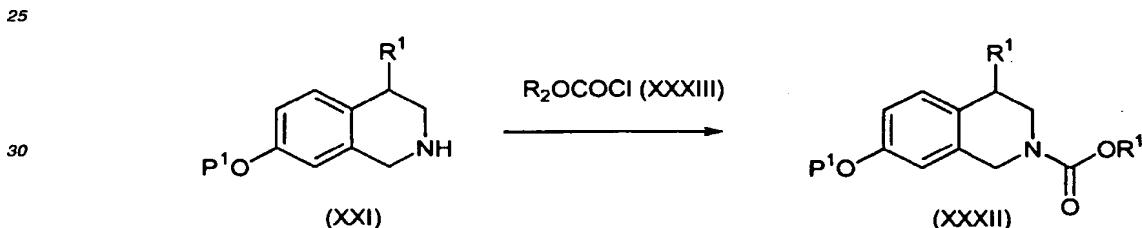

55 [0113] The compounds of formula (XXI) can be treated with an acid chloride of formula (XXVI) or an acid anhydride of formula (XXVII) in the presence a tertiary amine base such as triethylamine or DMAP to give an amide of formula (XXVIII). The acid chlorides of formula (XXVI) and acid anhydride of formula (XXVII) are commercially available or can be prepared from carboxylic acids by procedures known to those skilled in the art.

[0114] Another synthetic route for preparing the compounds of formula (XXVIII) involves treating a compound of formula (XXI), preferably at room temperature, with a carboxylic acid of formula (XXIX) in the presence of a coupling agent (e.g., dicyclohexylcarbodiimide (DCC), 1-(3'-dimethylaminopropyl)-3-ethylcarbodiimide (EDC), or 1-propanephosphonic acid cyclic anhydride (PPAA)) and a suitable base (e.g., triethylamine, DMAP, or N-methylmorpholine (NMO)) in a solvent such as dichloromethane, chloroform, or dimethylformamide. Optionally, agents such as HOBr may be added to the reaction.

[0115] Compounds of formula (XXX) can be prepared by reacting the amines of formula (XXI) with a sulfonyl chloride of formula (XXXI) in the presence of a base such as triethylamine, DMAP, or NMO in a suitable solvent such as dichloromethane, chloroform, or dimethylformamide. The reactions can be run in a temperature range of -20°C to 60°C, though room temperature is preferred.

[0116] Compounds of formula (XXXII) can be prepared by reacting the amines of formula (XXI) with a chloroformate of formula (XXXIII) in the presence of a base such as triethylamine, DMAP, NMO, or sodium hydrogen carbonate in a suitable solvent such as dichloromethane, chloroform, aqueous or anhydrous tetrahydrofuran, or dimethylformamide. The reaction can be run at 0°C to 60°C, though room temperature is preferred.

45

50

55

Scheme E

[0118] An alternative and more preferable synthesis of compounds of formula (XXI) involves reacting an alpha halogenated ketone of formula (XXXIV) with a suitably protected ammonia equivalent, preferably benzylamine, to give an amino-ketone of formula (XXXV). It will be obvious to anyone skilled in the art that the order of some of the next steps may be reversed. The compound of formula (XXXV) can be reduced with a suitable reducing agent, preferably sodium borohydride, di-isobutyl aluminum hydride (DIBAL-H), or lithium aluminum hydride in a suitable solvent. Typically, sodium borohydride reactions are run in protic solvents such as methanol or ethanol, in the temperature range of -10°C to 40°C (but preferably at about 0°C), and the DIBAL-H or lithium aluminum hydride reactions are preferably run in dichloromethane or THF in the temperature range of -78°C to 30°C (preferably at about 0°C) to give the amino alcohol of formula (XXXVI). In the next step, the amino alcohol of formula (XXXVI) is condensed with an aldehyde of formula (XXXVII) to give initially an iminium salt of formula (XXXVIII). The iminium salt of formula (XXXVIII) is reduced in situ with a reducing agent such as sodium borohydride, sodium cyanoborohydride, or sodium triacetoxyborohydride in a solvent such as dichloromethane, chloroform, 1,2 dichloroethane, methanol, or ethanol to give the amino alcohol of formula (XXXIX). For the latter reduction reaction, a temperature range of -10°C to 50°C can be employed but a temperature of about 0°C is preferred.

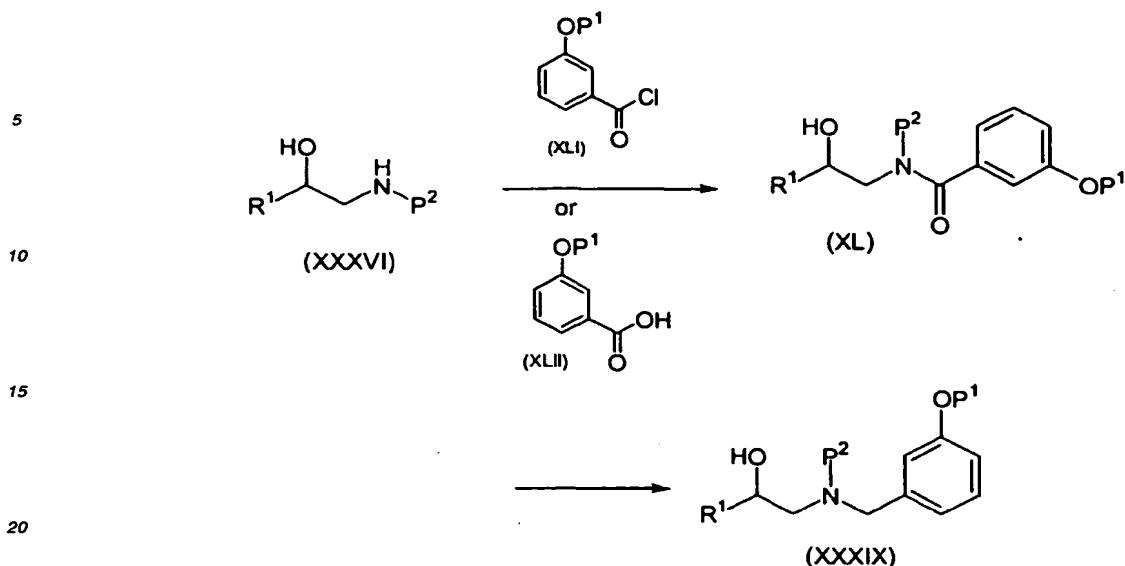

[0119] The amino alcohol of formula (XXXIX) can be cyclodehydrated in the presence of a strong acid such as sulfuric acid or trifluoroacetic acid in a solvent such as dichloromethane, chloroform, or 1,2 dichloroethane in a temperature range of 0°C to 60°C to give (after appropriate deprotection) the tetrahydroisoquinoline of formula (XXI).

General Reaction Scheme F

[0120] A compound of formula (XXIX) (i.e., the amino alcohol intermediary shown in Scheme E) may be prepared according to the alternative procedures illustrated in Scheme F.

Scheme F

- 25 [0121] Another option for the synthesis of amino alcohol of formula (XXXIX) is via the amide of formula (XL), which can be prepared by methods known to those of ordinary skill from the amino alcohol (XXXVI). Such methods may include taking the amino-alcohol of formula (XXXVI) and treating this with an acid chloride of formula (XLI) in the presence of a tertiary amine base such as triethylamine or DMAP. The acid chlorides of formula (XLI) are commercially available or can be prepared from carboxylic acids by procedures known to those of ordinary skill in the art. Another method of preparing the amides of formula (XL) involves treating an amino alcohol of formula (XXXVI) with a carboxylic acid of formula (XLII) in the presence of a coupling agent (e.g., DCC, EDC, or PPAA) and a suitable base (e.g., triethylamine, DMAP, or NMO) in a solvent such as dichloromethane, chloroform, or dimethylformamide. Optionally, agents such as HOBT maybe added to the reaction. Typically, the reaction is run in the temperature range of 0°C to 50°C, with room temperature being preferred.
- 30 [0122] The amides of formula (XL) can then be reduced to an amino-alcohol of formula (XXXIX) by reaction with a reducing agent such as lithium aluminum hydride or borane in a suitable solvent such as tetrahydrofuran or 1,2 dimethoxyethane at -10°C to 100°C (with 0°C being preferred).
- 35 [0123] Reactive groups not involved in the above processes can be protected with standard protecting groups during the reactions and removed by standard procedures (Greene & Wuts, Protecting Groups in Organic Synthesis, John Wiley and Sons, Inc., Interscience, 2nd edition, New York) known to those of ordinary skill in the art. Presently preferred protecting groups include methyl and benzyl for the hydroxyl moiety, and trifluoroacetamide and benzyl for the amino moiety.
- 40 [0124] In each of the general reaction schemes discussed or illustrated above, pressure is not critical unless otherwise indicated. Pressures from about 0.5 atmospheres (~50,000 Pa) to about 5 atmospheres (~500,000 Pa) are generally acceptable, and ambient pressure, i.e. about 1 atmosphere (~100,000 Pa), is preferred as a matter of convenience.
- 45 [0125] The compounds of this invention may be prepared in racemic form and be resolved into their component enantiomers by standard techniques such as fractional crystallization or preparative chromatography. Alternatively, enantiomers of the invention compounds may be synthesized from the appropriate optically active intermediates or starting materials using any of the general processes described herein.
- 50 [0126] Further, optically active compounds of this invention may be prepared using enantioselective reactions or by resolution techniques such as the preparation of diastereomers by reacting the racemic material with an optically active reagent.
- 55 [0127] The compounds of this invention are valuable estrogen agonists or antagonists, and thus valuable pharmaceutical agents. Those that are estrogen agonists are useful for oral contraception, relief of the symptoms of menopause, prevention of threatened or habitual abortion, relief of dysmenorrhea, relief of dysfunctional uterine bleeding, relief of endometriosis, an aid in ovarian development, treatment of acne, diminution of excessive growth of body hair in women (hirsutism), the prevention and/or treatment of cardiovascular disease, prevention and treatment of athero-

sclerosis, prevention and treatment of osteoporosis, treatment of benign prostatic hyperplasia and prostatic carcinoma, obesity, and suppression of post-partum lactation. These agents also have a beneficial effect on plasma lipid levels and as such are useful in treating and/or preventing hypercholesterolemia.

[0128] While the compounds of this invention are typically estrogen agonists in bone, unexpectedly they are also often antiestrogens in breast tissue and as such would be useful in the treatment and prevention of breast cancer.

[0129] While the compounds of this invention are expected to be sufficiently active if administered separately, in many instances it will be beneficial to combine these compounds with other compounds in order to even more effectively treat a disease or condition. Exemplary categories of compounds which will be beneficial in combination with the compounds of the present invention include an anabolic agent, a prodrug thereof, or a pharmaceutically acceptable salt of said anabolic agent or said prodrug; a growth hormone or a growth hormone secretagogue, a prodrug thereof, or a pharmaceutically acceptable salt of said growth hormone secretagogue or said prodrug; a prostaglandin agonist/antagonist, a prodrug thereof, or a pharmaceutically acceptable salt of said prostaglandin agonist/antagonist or said prodrug; or a parathyroid hormone or sodium fluoride.

[0130] It will also be useful to present the compounds of the present invention in the form of kits useful for treating or preventing a disease, disorder, condition, or symptom mediated by an estrogen receptor and/or caused by lowered estrogen levels, said kit comprising a compound of the present invention and a pharmaceutically acceptable vehicle, carrier, or diluent in a dosage form, and a container for containing said dosage form.

[0131] In many instances, it will be preferable for the kit to include, in addition to a compound of the present invention, an anabolic agent, a prodrug thereof, or a pharmaceutically acceptable salt of said anabolic agent or said prodrug; a growth hormone or a growth hormone secretagogue, a prodrug thereof, or a pharmaceutically acceptable salt of said growth hormone secretagogue or said prodrug; a prostaglandin agonist/antagonist, a prodrug thereof, or a pharmaceutically acceptable salt of said prostaglandin agonist/antagonist or said prodrug; or a parathyroid hormone or sodium fluoride.

25 Methods for Testing the Activity of Invention Compounds

Assay 1: Control and Prevention of Endometriosis

[0132] A preferred protocol for surgically inducing endometriosis is that described by Jones, *Acta Endocrinol (Copenh)*, 106:282-88 (1984). Adult Charles River Sprague-Dawley CD® female rats (200-240 g) are used. An oblique ventral incision is made through the skin and musculature of the body wall. A segment of the right uterine horn is excised, the myometrium is separated from the endometrium, and the segment is cut longitudinally. A 5x5 mm section of the endometrium, with the epithelial lining apposed to the body wall, is sutured at its four corners to the muscle using polyester braid (Ethiflex, 7-0®). The criterion of a viable graft is the accumulation of fluid similar to that which occurs in the uterus as a result of estrogen stimulation.

[0133] Three weeks after transplantation of the endometrial tissue (+3 weeks) the animals are laparotomized, the volume of the explant (length x width x height) in mm is measured with calipers, and treatment is begun. The animals are injected sc for 3 weeks with 10 to 1000 mg/kg/day of a test compound according to the present invention. Control animals bearing endometrial explants are injected sc with 0.1 ml/day of corn oil for 3 weeks. At the end of the 3 week treatment period (+6 weeks), the animals are laparotomized and the volume of the explant determined. Eight weeks after cessation of treatment (+14 weeks) the animals are sacrificed and the explants are measured again. Statistical analysis of the explant volume is by an analysis of variance.

45 Assay 2: Effect on Prostate Weight

[0134] Three-month-old male Sprague-Dawley rats are administered by subcutaneous injection control vehicle (10% ethanol in water), estradiol (30 µg/kg), testosterone (1 mg/kg), or a test compound according to the present invention daily for 14 days (n=6/group). After 14 days the animals are sacrificed, the prostate is removed, and the wet prostate weight is determined. Mean weight is determined and statistical significance ($p<0.05$) is determined compared to the vehicle-treated group using the Student's t-test.

[0135] Active compounds significantly ($P<0.05$) decrease prostate weight compared to controls. Testosterone is expected to have no effect while estrogen at 30 µg/kg is expected to significantly reduce prostate weight.

55 Assay 3: In Vitro Estrogen Receptor Binding

[0136] An *in vitro* estrogen receptor binding assay that measures the ability of the compounds of the present invention to displace [³H]-estradiol from human estrogen receptor obtained by recombinant methods in yeast, bacteria, or mammalian cells is used to determine the estrogen receptor binding affinity of the compounds of this invention. The materials

used in this assay are: (1) TD-0.3 assay buffer (containing 10 mM Tris, pH 7.6, 0.3 M potassium chloride, and 5mM DTT); (2) the radioligand used is [³H]-estradiol obtained from New England Nuclear (Boston, MA); (3) the cold ligand used is estradiol obtained from Sigma (St. Louis, MO); and (4) recombinant human estrogen receptor, hER.

[0137] A solution of the compound being tested is prepared in TD-0.3 with 4% DMSO and 16% ethanol. The tritiated estradiol is dissolved in TD-0.3 such that the final concentration in the assay is 5 nM. The hER is also diluted with TD-0.3 such that 0.2 nM hER is in each assay well. Using microtitre plates, each incubate receives 50 µl of cold estradiol (nonspecific binding) or the test compound solution, 20 µl of the tritiated estradiol, and 30 µl of hER solutions. Each plate contains varying concentrations of the compound and total binding controls in triplicate. The plates are incubated overnight at 4°C. The binding reaction is then terminated by the addition and mixing of 100 µl of 3% hydroxylapatite in 10 mM Tris, pH 7.6, followed by incubation for 15 minutes at 4°C. The mixture is centrifuged and the pellet washed four times with 1% Triton-X100 in 10 mM Tris, pH 7.6. The hydroxylapatite pellets are suspended in Ecolite (+) (ICN Biomedicals, Inc., Aurora, OH) and radioactivity is assessed using beta scintigraphy. The mean of all triplicate data points (counts per minute, cpm's) is determined. Specific binding is calculated by subtracting nonspecific cpm's (defined as counts that remain following separation of reaction mixture containing recombinant receptor, radioligand, and excess unlabeled ligand) from total bound cpm's (defined as counts that remain following the separation of reaction mixture containing only recombinant receptor, radioligand). Test compound potency is determined by means of IC₅₀ determinations (the concentration of a test compound needed to inhibit 50% of the total specific tritiated estradiol bound). Specific binding in the presence of varying concentrations of test compound is determined and calculated as percent specific binding of total specific radioligand bound. Data are plotted as percent inhibition by test compound (linear scale) versus test compound concentration (log scale).

Assay 4: Effect on Total Cholesterol Levels

[0138] The effect of the compounds of the present invention on plasma levels of total cholesterol is measured as follows. Blood samples are collected via cardiac puncture from anesthetized female (Sprague-Dawley) rats 4-6 months of age that are bilaterally ovariectomized and treated with the test compound (10-1000 µg/kg/day, for example, sc or orally for 28 days or with control vehicle for the same time), or sham operated. The blood is placed in a tube containing 30 µl of 5% EDTA (10 µl EDTA/1 ml of blood). After centrifugation at 2500 rpm for 10 minutes at 20°C the plasma is removed and stored at -20°C. The total cholesterol is assayed using a standard enzymatic determination kit from Sigma Diagnostics (Procedure No. 352).

Assay 5: Effect on Obesity

[0139] Ten-month-old female Sprague-Dawley rats, weighing approximately 450 grams, are sham-operated or ovariectomized and treated orally with vehicle, 17 α -ethynodiol at 30 mg/kg/day, or a compound according to the present invention at 10-1000 mg/kg/day for 8 weeks. There are 6 to 7 rats in each sub group. On the last day of the study, body composition of all rats is determined via dual energy x-ray absorptiometry using a Hologic QDR-1000/W (Hologic, Bedford, MA) equipped with whole body scan software that shows the proportions of fat body mass and lean body mass.

[0140] A decrease in fat body mass indicates that the test compound is useful in preventing and treating obesity.
